Machine Learning

Lab: 1

Introduction to Machine Learning Libraries in Python

December 2024

Perform Date: December 02-06, 2024

**Objective** 1

To introduce different machine learning libraries available in python.

2 **Description** 

Python is the preferred language in Machine Learning. The availability of libraries and open-

source tools make it ideal choice for developing ML models. Python offers some of the best

flexibilities and features to developers that not only increase their productivity but the quality

of the code as well, not to mention the extensive libraries that help ease the workload. In this

lab we will get introduced to some of the python libraries useful in Machine learning model

development.

**Implementation GuideLines** 3

3.1 **Linear Algebra in Python with Numpy** 

Numpy is one of the most used libraries in Python for arrays manipulation. It adds to Python a

set of functions that allows us to operate on large multidimensional arrays with just a few lines.

2

```
[ ]: import numpy as np
```

## 3.1.1 Defining lists and numpy arrays

Note the difference between a Python list and a NumPy array.

#### 3.1.2 Algebraic operators on NumPy arrays vs. Python lists

Note that the '+' operator on NumPy arrays perform an element-wise addition, while the same operation on Python lists results in a list concatenation.

```
[]: print(narray + narray)
    print(alist + alist)

[2 4 6 8]
    [1, 2, 3, 4, 5, 1, 2, 3, 4, 5]

[]: print(narray + narray1) #operands needs to be of same shape
    print(alist + alist)

[]: alist1 = [1, 2, 3, 4]

[]: print(alist + alist1)

[1, 2, 3, 4, 5, 1, 2, 3, 4]
```

It is the same as with the product operator, \*. In the first case, we scale the vector, while in the second case, we concatenate three times the same list.

```
[ ]: print(narray * 3)
    print(alist * 3)

[ 3 6 9 12]
    [1, 2, 3, 4, 5, 1, 2, 3, 4, 5, 1, 2, 3, 4, 5]
```

#### 3.1.3 Array math

Basic mathematical functions operate elementwise on arrays, and are available both as operator overloads and as functions in the numpy module:

```
[]: x = np.array([[1,2],[3,4]], dtype=np.float64)
y = np.array([[5,6],[7,8]], dtype=np.float64)

# Elementwise sum; both produce the array
print(x + y)
```

```
print(np.add(x, y))
    [[ 6. 8.]
    [10. 12.]]
    [[ 6. 8.]
     [10. 12.]]
[ ]: # Elementwise difference; both produce the array
    print(x - y)
    print(np.subtract(x, y))
    [ [-4. -4.]
    [-4. -4.]
    [ [-4. -4.]
     [-4. -4.]
[]: # Elementwise product; both produce the array
    print (x * y)
    print(np.multiply(x, y))
    [[ 5. 12.]
    [21. 32.]]
    [[ 5. 12.]
     [21. 32.]]
[ ]: print(x.dot(y))
    [[19 22]
     [43 50]]
[]: # Elementwise division; both produce the array
    # [[ 0.2
                    0.333333333
     # [ 0.42857143 0.5 ]]
    print(x / y)
    print(np.divide(x, y))
    [[0.2
                 0.33333333]
```

]]

[0.42857143 0.5

```
[[0.2
          0.333333331
     [0.42857143 0.5
                      11
[]: # Elementwise square root; produces the array
     # [[ 1.
                     1.41421356]
     # [ 1.73205081 2. ]]
    print(np.sqrt(x))
                 1.41421356]
    [[1.
     [1.73205081 2.
                            11
[]: x = np.array([[1,2],[3,4]])
    y = np.array([[5, 6], [7, 8]])
    v = np.array([9,10])
    w = np.array([11, 12])
    # Inner product of vectors; both produce 219
    print(v.dot(w))
    print(np.dot(v, w))
    219
    219
    You can also use the @ operator which is equivalent to numpy's dot operator.
[ ]: print(v @ w)
    219
[]: # Matrix / vector product; both produce the rank 1 array [29]

→ 67]

    print(x.dot(v))
    print(np.dot(x, v))
    print(x @ v)
```

```
[29. 67.]
[29. 67.]
[29. 67.]
[]: # Matrix / matrix product; both produce the rank 2 array
# [[19 22]
# [43 50]]
print(x.dot(y))
print(np.dot(x, y))
print(x @ y)

[[19. 22.]
[43. 50.]]
[[19. 22.]
[43. 50.]]
[[19. 22.]
[43. 50.]]
```

Numpy provides many useful functions for performing computations on arrays; one of the most useful is sum:

```
[]: x = np.array([[1,2],[3,4]])

print(np.sum(x)) # Compute sum of all elements; prints "10"

print(np.sum(x, axis=0)) # Compute sum of each column;

prints "[4 6]"

print(np.sum(x, axis=1)) # Compute sum of each row; prints

print(np.sum(x, axis=1)) # Compute sum of each row; prints
```

10[4 6][3 7]

You can find the full list of mathematical functions provided by numpy in the documentation.

Apart from computing mathematical functions using arrays, we frequently need to reshape

or otherwise manipulate data in arrays. The simplest example of this type of operation is transposing a matrix; to transpose a matrix, simply use the T attribute of an array object:

```
[]: print(x)
    print("transpose\n", x.T)

[[1 2]
    [3 4]]
    transpose
    [[1 3]
    [2 4]]

[]: v = np.array([[1,2,3]])
    print(v)
    print("transpose\n", v.T)

[[1 2 3]]
    transpose
    [[1]
    [2]
    [3]]
```

#### 3.1.4 Matrix or Array of Arrays

With NumPy, we have two ways to create a matrix: \* Creating an array of arrays using np.array (recommended). \* Creating a matrix using np.matrix (still available but might be removed soon).

```
print(npmatrix1)
print(npmatrix2)
print(npmatrix3)

[[1 2 3 4]
  [1 2 3 4]
  [1 2 3 4]
[[1 2 3 4 5]
  [1 2 3 4 5]
  [1 2 3 4 5]
  [1 2 3 4 5]]
[[1 2 3 4]
  [1 1 1]
  [1 2 3 4]]
```

However, when defining a matrix, be sure that all the rows contain the same number of elements. Otherwise, the linear algebra operations could lead to unexpected results.

Analyze the following two examples:

```
print(badmatrix) # Print the malformed matrix

print(badmatrix * 2) # It is supposed to scale the whole.

→matrix
```

```
[list([1, 2]) list([3, 4]) list([6, 7, 8])]
[list([1, 2, 1, 2]) list([3, 4, 3, 4]) list([6, 7, 8, 6, 7, □ →8])]
```

#### 3.1.5 Scaling and translating matrices

Now that you know how to build correct NumPy arrays and matrices, let us see how easy it is to operate with them in Python using the regular algebraic operators like + and -.

Operations can be performed between arrays and arrays or between arrays and scalars.

```
[]: # Scale by 2 and translate 1 unit the matrix
    result = okmatrix * 2 + 1 # For each element in the matrix,
     →multiply by 2 and add 1
    print (result)
    [[3 5]
     [7 9]]
[ ]: # Add two sum compatible matrices
    result1 = okmatrix + okmatrix
    print (result1)
     # Subtract two sum compatible matrices. This is called the
     →difference vector
    result2 = okmatrix - okmatrix
    print(result2)
    [[2 4]
     [6 8]]
    [[0 0]]
     [0 0]]
```

The product operator \* when used on arrays or matrices indicates element-wise multiplications. Do not confuse it with the dot product.

```
[]: result = okmatrix * okmatrix # Multiply each element by → itself
print(result)

[[1 4]
[9 16]]
```

#### 3.1.6 Transpose a matrix

In linear algebra, the transpose of a matrix is an operator that flips a matrix over its diagonal, i.e., the transpose operator switches the row and column indices of the matrix producing another matrix. If the original matrix dimension is n by m, the resulting transposed matrix will be m by n.

T denotes the transpose operations with NumPy matrices.

However, note that the transpose operation does not affect 1D arrays.

```
[]: nparray = np.array([1, 2, 3, 4]) # Define an array
     print('Original array')
     print (nparray)
     print('Transposed array')
     print (nparray.T)
    Original array
    [1 2 3 4]
    Transposed array
    [1 2 3 4]
    perhaps in this case you wanted to do:
[]: nparray = np.array([[1, 2, 3, 4]]) # Define a 1 x 4 matrix...
     →Note the 2 level of square brackets
     print('Original array')
     print (nparray)
     print('Transposed array')
     print (nparray.T)
    Original array
```

```
Original array
[[1 2 3 4]]
Transposed array
[[1]
[2]
[3]
[4]]
```

## 3.1.7 Get the norm of a nparray or matrix

In linear algebra, the norm of an n-dimensional vector  $\vec{a}$  is defined as:

$$norm(\vec{a}) = ||\vec{a}|| = \sqrt{\sum_{i=1}^{n} a_i^2}$$

Calculating the norm of vector or even of a matrix is a general operation when dealing with

Computer Engineering Department, Faculty of Technology, D. D. University Page 12 of 154

data. Numpy has a set of functions for linear algebra in the subpackage **linalg**, including the **norm** function. Let us see how to get the norm a given array or matrix:

```
[]: nparray1 = np.array([1, 2, 3, 4]) # Define an array
norm1 = np.linalg.norm(nparray1)

nparray2 = np.array([[1, 2], [3, 4]]) # Define a 2 x 2.

-matrix. Note the 2 level of square brackets
norm2 = np.linalg.norm(nparray2)

print(norm1)
print(norm2)
```

- 5.477225575051661
- 5.477225575051661

Note that without any other parameter, the norm function treats the matrix as being just an array of numbers. However, it is possible to get the norm by rows or by columns. The **axis** parameter controls the form of the operation: \* **axis=0** means get the norm of each column \* **axis=1** means get the norm of each row.

```
[3.74165739 3.74165739]
[1.41421356 2.82842712 4.24264069]
```

#### 3.1.8 The dot product between arrays: All the flavors

The dot product or scalar product or inner product between two vectors  $\vec{a}$  and  $\vec{a}$  of the same size is defined as:

$$\vec{a} \cdot \vec{b} = \sum_{i=1}^{n} a_i b_i$$

The dot product takes two vectors and returns a single number.

38

38

38

38

Recommend np.dot: since it is the only method that accepts arrays and lists without problems

Finally, note that the norm is the square root of the dot product of the vector with itself.

$$norm(\vec{a}) = ||\vec{a}|| = \sqrt{\sum_{i=1}^{n} a_i^2} = \sqrt{a \cdot a}$$

### 3.1.9 Sums by rows or columns

Another general operation performed on matrices is the sum by rows or columns. Just as we did for the function norm, the **axis** parameter controls the form of the operation: \* **axis=0** means to sum the elements of each column together. \* **axis=1** means to sum the elements of each row together.

```
Sum by columns:
[ 6 -6]
Sum by rows:
```

[0 0 0]

#### 3.1.10 Get the mean by rows or columns

As with the sums, one can get the **mean** by rows or columns using the **axis** parameter. Just remember that the mean is the sum of the elements divided by the length of the vector

$$mean(\vec{a}) = \frac{\sqrt{\sum_{i=1}^{n} a_i}}{n}$$

```
Matrix mean:

0.0

Mean by columns:

[ 2. -2.]

Mean by rows:

[0. 0. 0.]
```

#### 3.1.11 Center the columns of a matrix

Centering the attributes of a data matrix is another essential preprocessing step. Centering a matrix means to remove the column mean to each element inside the column. The sum by columns of a centered matrix is always 0.

With NumPy, this process is as simple as this:

```
[]: nparray2 = np.array([[1, 1], [2, 2], [3, 3]]) # Define a 3 x_{a}
     \rightarrow 2 matrix.
     nparrayCentered = nparray2 - np.mean(nparray2, axis=0) #___
      →Remove the mean for each column
     print('Original matrix')
     print (nparray2)
     print('Centered by columns matrix')
     print (nparrayCentered)
     print('New mean by column')
     print (nparrayCentered.mean (axis=0))
    Original matrix
    [[1 \ 1]
     [2 2]
     [3 3]]
    Centered by columns matrix
    [[-1. -1.]
     [ 0. 0.]
     [ 1. 1.]]
    New mean by column
    [0.0.]
```

**Warning:** This process does not apply for row centering. In such cases, consider transposing the matrix, centering by columns, and then transpose back the result.

See the example below:

```
[]: nparray2 = np.array([[1, 3], [2, 4], [3, 5]]) # Define a 3 x_{a}
     →2 matrix.
    nparrayCentered = nparray2.T - np.mean(nparray2, axis=1) #__
     →Remove the mean for each row
    nparrayCentered = nparrayCentered.T # Transpose back the_
     →result
    print('Original matrix')
    print (nparray2)
    print('Centered by columns matrix')
    print (nparrayCentered)
    print('New mean by rows')
    print (nparrayCentered.mean (axis=1))
    Original matrix
    [[1 3]
     [2 4]
     [3 5]]
    Centered by columns matrix
    [[-1. 1.]
     [-1. 1.]
     [-1. 1.]
    New mean by rows
    [0. 0. 0.]
```

# 3.2 NLTK Library

The Natural Language Toolkit (NLTK) is a platform used for building Python programs that work with human language data for applying in statistical natural language processing (NLP). It contains text-processing libraries for tokenization, parsing, classification, stemming, tagging and semantic reasoning.

### 3.2.1 Preprocessing

In this lab, we will be exploring how to preprocess tweets for sentiment analysis. We use the NLTK package to perform a preprocessing pipeline for Twitter datasets.

#### 3.2.2 About the Twitter dataset

The dataset contains 5000 positive tweets and 5000 negative tweets exactly. (Not a Real World Scenario !!!)

```
[]: #downloads sample twitter dataset.
    nltk.download('twitter_samples')

[nltk_data] Downloading package twitter_samples to /root/
    →nltk_data...
[nltk_data] Unzipping corpora/twitter_samples.zip.
[]: True
```

We can load the text fields of the positive and negative tweets by using the module's strings() method like this:

Computer Engineering Department, Faculty of Technology, D. D. University Page 19 of 154

```
[]: # select the set of positive and negative tweets
    all_positive_tweets = twitter_samples.

→strings('positive_tweets.json')
    all_negative_tweets = twitter_samples.
     →strings('negative_tweets.json')
[]: print('Number of positive tweets: ',_
     →len(all_positive_tweets))
    print('Number of negative tweets: ',,,
     →len(all_negative_tweets))
    print('\nThe type of all_positive_tweets is: ',...
     →type(all_positive_tweets))
    print('The type of a tweet entry is: ',_
     →type(all_negative_tweets[0]))
    Number of positive tweets: 5000
    Number of negative tweets: 5000
    The type of all_positive_tweets is: <class 'list'>
    The type of a tweet entry is: <class 'str'>
```

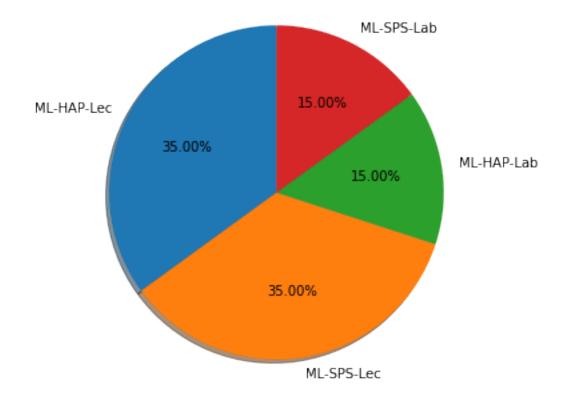

We can see that the data is stored in a list and individual tweets are stored as strings.

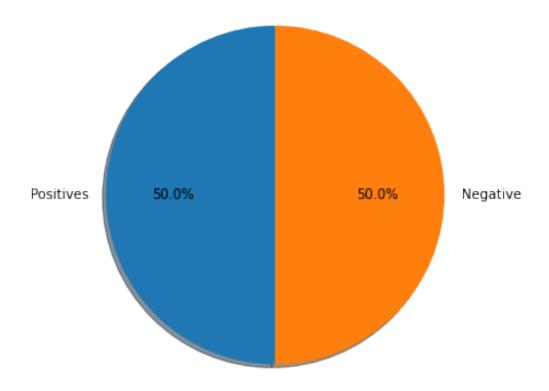

Let's have more visually appealing report by using Matplotlib's pyplot library.

```
[]: # Declare a figure with a custom size
fig = plt.figure(figsize=(5, 5))

# labels for the classes
labels = 'ML-HAP-Lec', 'ML-SPS-Lec', 'ML-HAP-Lab', 'ML-SPS-Lab'

# Sizes for each slide
sizes = [35, 35, 15,15]
```

# 3.2.3 Looking at raw texts

duh emesh :p https://t.co/FtiAVocFll

#### @Atunci\_CoV @QuetaAuthor :( rude

Here is a list of some common colors you can use:

Red = '\033[91m' Green = '\033[92m' Blue = '\033[94m' Cyan = '\033[96m' White = '\033[97m' Yellow = '\033[93m' Magenta = '\033[95m' Grey = '\033[90m' Black = '\033[90m' Default = '\033[99m'

Computer Engineering Department, Faculty of Technology, D. D. University Page 23 of 154

One observation you may have is the presence of emoticons and URLs in many of the tweets.

## 3.2.4 Preprocess raw text for Sentiment analysis

## **Data preprocessing:**

For NLP, the preprocessing steps are comprised of the following tasks:

- Tokenizing the string
- Lowercasing
- Removing stop words and punctuation

tweet = all\_positive\_tweets[2277]

• Stemming

[ ]: # Our selected sample

print(tweet)

Let's see how we can do these to a given tweet. We will choose just one and see how this is transformed by each preprocessing step.

```
My beautiful sunflowers on a sunny Friday morning off :) _
     →#sunflowers #favourites
    #happy #Friday off... https://t.co/3tfYomON1i
    Let's import a few more libraries for this purpose.
[ ]: # download the stopwords from NLTK
     nltk.download('stopwords')
    [nltk_data] Downloading package stopwords to /root/
     →nltk_data...
    [nltk_data] Unzipping corpora/stopwords.zip.
[]: True
[ ]: import re
                                                  # library for...
     →regular expression operations
                                                  # for string
     import string
      →operations
```

## 3.2.5 Remove hyperlinks, Twitter marks and styles

Since we have a Twitter dataset, we'd like to remove some substrings commonly used on the platform like the hashtag, retweet marks, and hyperlinks. We'll use the re library to perform regular expression operations on our tweet. We'll define our search pattern and use the sub() method to remove matches by substituting with an empty character (i.e. '')

```
[]: print('\033[94m')

# remove hyperlinks

tweet2 = re.sub(r'https?:\/\/.*[\r\n]*', '', tweet)

# remove hashtags
# only removing the hash # sign from the word

tweet2 = re.sub(r'#', '', tweet2)
print(tweet2)
```

```
My beautiful sunflowers on a sunny Friday morning off :) → #sunflowers

#favourites #happy #Friday off... https://t.co/3tfYomON1i

My beautiful sunflowers on a sunny Friday morning off :) → sunflowers favourites

happy Friday off...
```

## 3.2.6 Tokenize the string

To tokenize means to split the strings into individual words without blanks or tabs. In this same step, we will also convert each word in the string to lower case. The tokenize module from NLTK allows us to do these easily:

```
[]: print()
  print('\033[92m' + tweet2)
  print('\033[94m')

# instantiate tokenizer class
  tokenizer = TweetTokenizer(preserve_case=False)

# tokenize tweets
  tweet_tokens = tokenizer.tokenize(tweet2)

print()
  print('Tokenized string:')
  print(tweet_tokens)
```

```
My beautiful sunflowers on a sunny Friday morning off :)

sunflowers

favourites happy Friday off...

Tokenized string:
['my', 'beautiful', 'sunflowers', 'on', 'a', 'sunny',

s'friday', 'morning',

'off', ':)', 'sunflowers', 'favourites', 'happy', 'friday',

s'off', '...']
```

#### 3.2.7 Remove stop words and punctuations

The next step is to remove stop words and punctuation. Stop words are words that don't add significant meaning to the text.

```
[]: #Import the english stop words list from NLTK
stopwords_english = stopwords.words('english')

print('Stop words\n')
print(stopwords_english)

print('\nPunctuation\n')
print(string.punctuation)
```

Stop words

Computer Engineering Department, Faculty of Technology, D. D. University Page 27 of 154

```
'its', 'itself', 'they', 'them', 'their', 'theirs',
'which', 'who', 'whom', 'this', 'that', "that'll", 'these',
→'those', 'am', 'is',
'are', 'was', 'were', 'be', 'been', 'being', 'have', 'has',
→'had', 'having',
'do', 'does', 'did', 'doing', 'a', 'an', 'the', 'and', 'but',
→'if', 'or',
'because', 'as', 'until', 'while', 'of', 'at', 'by', 'for',...
→'with', 'about',
'against', 'between', 'into', 'through', 'during', 'before',
→'after', 'above',
'below', 'to', 'from', 'up', 'down', 'in', 'out', 'on',...
⇔'off', 'over', 'under',
'again', 'further', 'then', 'once', 'here', 'there', 'when',...
→'where', 'why',
'how', 'all', 'any', 'both', 'each', 'few', 'more', 'most',
→'other', 'some',
'such', 'no', 'nor', 'not', 'only', 'own', 'same', 'so', _
→'than', 'too', 'very',
's', 't', 'can', 'will', 'just', 'don', "don't", 'should', _
→"should've", 'now',
'd', 'll', 'm', 'o', 're', 've', 'y', 'ain', 'aren',
→"aren't", 'couldn',
"couldn't", 'didn', "didn't", 'doesn', "doesn't", 'hadn', "
→"hadn't", 'hasn',
"hasn't", 'haven', "haven't", 'isn', "isn't", 'ma', 'mightn',
→"mightn't",
'mustn', "mustn't", 'needn', "needn't", 'shan', "shan't",
→'shouldn',
```

```
"shouldn't", 'wasn', "wasn't", 'weren', "weren't", 'won',

→"won't", 'wouldn',

"wouldn't"]

Punctuation
!"#$%&'()*+,-./:;<=>?@[\]^_`{|}~
```

We can see that the stop words list above contains some words that could be important in some contexts.

These could be words like *i*, not, between, because, won, against.

You might need to customize the stop words list for some applications.

For our exercise, we will use the entire list.

For the punctuation, certain token like ':)' should be retained when dealing with tweets because they are used to express emotions.

```
print (tweets_clean)
```

```
['my', 'beautiful', 'sunflowers', 'on', 'a', 'sunny',

→'friday', 'morning',

'off', ':)', 'sunflowers', 'favourites', 'happy', 'friday',

→'off', '...']

removed stop words and punctuation:
['beautiful', 'sunflowers', 'sunny', 'friday', 'morning', ':

→)', 'sunflowers',

'favourites', 'happy', 'friday', '...']
```

### 3.2.8 Stemming

Stemming is the process of converting a word to its most general form, or stem. This helps in reducing the size of our vocabulary.

Consider the words: \* learn \* learning \* learned \* learnt

All these words are stemmed from its common root learn.

However, in some cases, the stemming process produces words that are not correct spellings of the root word. For example, **happi** and **sunni**. That's because it chooses the most common stem for related words. For example, we can look at the set of words that comprises the different forms of happy:

- happy
- happiness
- happier

We can see that the prefix **happi** is more commonly used. We cannot choose **happ** because it is the stem of unrelated words like **happen**.

NLTK has different modules for stemming and we will be using the PorterStemmer

Computer Engineering Department, Faculty of Technology, D. D. University Page 30 of 154

```
[ ]: words =['happier', 'happiness', 'happy', 'studying', 'study',
     ' studies','meeting']
[ ]: print()
    print('\033[92m')
    print (tweets_clean)
    print('\033[94m')

# 3.3 Pandas Library

Python Pandas is defined as an open-source library that provides high-performance data manipulation in Python. Pandas is built on top of the Numpy package, means Numpy is required for operating the Pandas. Pandas enhanced data analysis capabilities of python. It can perform five significant steps required for processing and analysis of data irrespective of the origin of the data, i.e., load, manipulate, prepare, model, and analyze.

Pandas library of python is very useful for the manipulation of mathematical data and is widely used in the field of machine learning. It comprises of many methods for its proper functioning. loc() and iloc() are one of those methods. These are used in slicing of data from the Pandas DataFrame. They help in the convenient selection of data from the DataFrame. They are used in filtering the data according to some conditions.

**loc()**: loc() is label based data selecting method which means that we have to pass the name of the row or column which we want to select.

**iloc():** iloc() is a indexed based selecting method which means that we have to pass integer index in the method to select specific row/column.

# 3.4 Scikit Learn Library

Scikit-learn (Sklearn) is the most useful and robust library for machine learning in Python. It provides a selection of efficient tools for machine learning and statistical modeling including classification, regression, clustering and dimensionality reduction via a consistence interface in Python. This library, which is largely written in Python, is built upon NumPy, SciPy and Matplotlib.

```
[]: #Import the relevant libraries and read the dataset

[]: import numpy as np
    import matplotlib as plt

from sklearn import datasets #various toy datasets

from sklearn import metrics #Check accuracy of model
```

```
from sklearn.linear_model import LogisticRegression #various_
→supervised and unsupervised learning algorithms
```

#### **Dataset Loading**

[[5.1 3.5 1.4 0.2]

```
[]: iris = datasets.load_iris()
```

**Features** The variables of data are called its features. They are also known as predictors, inputs or attributes.

**Feature matrix** It is the collection of features, in case there are more than one.

**Feature Names** It is the list of all the names of the features.

**Response** It is the output variable that basically depends upon the feature variables. They are also known as target, label or output.

**Response Vector** It is used to represent response column. Generally, we have just one response column.

**Target Names** It represent the possible values taken by a response vector.

```
[]: X = iris.data
y= iris.target

feature_names = iris.feature_names
target_names = iris.target_names
print("Feature names:", feature_names)
print("Target names:", target_names)
print("\nFirst 10 rows of X:\n", X[:10])

Feature names: ['sepal length (cm)', 'sepal width (cm)',
    'petal length (cm)',
    'petal width (cm)']
Target names: ['setosa' 'versicolor' 'virginica']

First 10 rows of X:
```

Computer Engineering Department, Faculty of Technology, D. D. University Page 46 of 154

```
[4.9 3. 1.4 0.2]

[4.7 3.2 1.3 0.2]

[4.6 3.1 1.5 0.2]

[5. 3.6 1.4 0.2]

[5.4 3.9 1.7 0.4]

[4.6 3.4 1.4 0.3]

[5. 3.4 1.5 0.2]

[4.4 2.9 1.4 0.2]

[4.9 3.1 1.5 0.1]]
```

To check the accuracy of our model, we can split the dataset into two pieces-a training set and a testing set. Use the training set to train the model and testing set to test the model. After that, we can evaluate how well our model did.

## 4 Exercise

#### **Exercise for Numpy Library:**

- 1) Create Two numpy array of size 4 X 5 and 5 X 4.
- 2) Randomly Initalize that array
- 3) Perform matrix multiplication
- 4) Perform elementwise matrix multiplication
- 5) Find mean, median of the first matrix.
- 6) Get the transpose of that Matrix that you created. Create a square matrix and find its determinant.
- 7) Obtain only the second column of the first array.

8) Convert Numeric entries(columns) of mtcars.csv to Mean Centered Version

**Exercise for NLTK Library:** Perform all text preprocessing tasks on Movie Review Dataset https://www.cs.cornell.edu/people/pabo/movie-review-data/

#### **Exercise for Pandas Library:**

- 1. Draw Scatter Plot between SepalLengthCm and SepalWidthCm for "Iris.csv" file with proper labeling.
- 2. Draw Histogram of SepalLengthCm with proper labeling.
- 3. Plot bar chart of Species.
- 4. Count total null values for each column in this dataset.
- 5. i) Print first 5 rows of SepalLengthCm. ii) Print from 5th row onwards all columns of Iris.csv dataset.

**Exercise for Scikit Learn Library:** Perform the mentioned steps of the Implementation Guidelines on Breast Cancer Dataset of Scikit Learn Library.

## 5 Exercise 1.1

- 1. Why the need for numpy arrays? Can't we just use Python lists?
- 2. Write the function to generate random numbers from a normal distribution with mean 0 and variance 1.
- 3. Create a 1D array **arr1** with 10 elements.
  - (a) Slice this array starting from 3rd value to the end.
  - (b) What is the result if you perform the following slicing on the given array. arr1[-4:-2]
- 4. Create two numpy arrays of size 4 x 4. Write functions used to calculate determinant of matrix, transpose of a matrix, norm of a matrix and to perform matrix multiplication. Write all the results.
- 5. Describe the dataset used for NLTK Lab exercise Task.

- 6. Show and compare the results generated by PorterStemmer and WordNetLemmatizer on any sample tweet from twitter dataset.
- 7. Describe the dataset used for Pandas Lab exercise Task. Write the function used to select rows from 1 to 4 and columns from 2 to 4 for iris dataset. Write the results.
- 8. Describe the dataset used for sklearn lab exercise task. Write the function used to divide the dataset into training and testing and descibe its parameters.
